7 Displacement of reference points

Models describing the displacements of reference points due to various effects are provided. In the following, three kinds of displacements are distinguished:

- Conventional displacements of reference markers on the crust (see Section 7.1) relate the regularized positions $X_R(t)$ of the reference points (see Chapter 4) to their conventional instantaneous positions. Generally these conventional instantaneous positions are used in data analyses as a priori coordinates for subsequent adjustment of observational data. They include tidal motions (mostly near diurnal and semidiurnal frequencies) and other accurately modeled displacements of reference markers (mostly at longer periods);

- Other displacements of reference markers (Section 7.2, presently, at the time of publication, under development) include non-tidal motions associated with changing environmental loads (very broad spectral content);

- Displacements that affect the internal reference points within the observing instruments, which are generally technique-dependent, are mentioned in Section 7.3.

The first two categories of displacements are described by geophysical models or gridded convolution results derived from geophysical models. The last category includes empirical physical effects that have been demonstrated to affect geodetic observing instruments.

As the non-tidal load displacements (Section 7.2) normally change very little over typical integration spans and because models for these effects are usually less accurate, it is generally recommended that they not be included in computing conventional instantaneous positions. Instead, the corresponding non-tidal loading effects will remain as signals embedded in the geodetic time series results. These signals can be extracted and compared with the model results referenced here in post-analysis studies.

In combinations of diverse analysis results, it is particularly important that equivalent displacement models are applied for like effects. Non-tidal load displacements should be consistently excluded from the conventional instantaneous positions, as recommended here, or else the same geophysical loading models together with the same environmental inputs should be applied.

7.1 Models for conventional displacement of reference markers on the crust

This section describes conventional models for displacement due to the body tides arising from the direct effect of the external tide generating potential (7.1.1), displacement due to ocean tidal loading (7.1.2) and due to diurnal and semidiurnal atmospheric pressure loading (7.1.3), displacement due to the centrifugal perturbations caused by Earth rotation variations, including the pole tide (7.1.4) and the loading caused by the ocean pole tide (7.1.5).

7.1.1 Effects of the solid Earth tides

7.1.1.1 Conventional model for solid Earth tides

Site displacements caused by tides of spherical harmonic degree and order $(nm)$ are characterized by the Love number $h_{nm}$ and the Shida number $l_{nm}$. The effective values of these numbers depend on station latitude and tidal frequency (Wahr, 1981). The latitude dependence and a small interband variation are caused by the Earth’s ellipticity and the Coriolis force due to Earth rotation. A strong frequency dependence within the diurnal band is produced by the Nearly Diurnal Free Wobble resonance associated with the FCN in the wobbles of the Earth and its core regions which contribute to the tidal deformations via their centrifugal effects. Additionally, the resonance in the deformation due to ocean tidal loading, which is not included in the computations of the last section which use constant load Love numbers, may be represented in terms of effective contributions to $h_{21}$ and $l_{21}$. A further
frequency dependence, which is most pronounced in the long-period tidal band, arises from mantle anelasticity leading to corrections to the elastic Earth Love numbers. The contributions to the Love number parameters from anelasticity and ocean tidal loading as well as those from the centrifugal perturbations due to the wobbles have imaginary parts which cause the tidal displacements to lag slightly behind the tide generating potential. All these effects need to be taken into account when an accuracy of 1 mm is desired in determining station positions.

In order to account for the latitude dependence of the effective Love and Shida numbers, the representation in terms of multiple $h$ and $l$ parameters employed by Mathews et al. (1995) is used. In this representation, parameters $h^{(0)}$ and $l^{(0)}$ play the roles of $h_2m$ and $l_2m$, while the latitude dependence is expressed in terms of additional parameters $h^{(2)}$, $h^{(2)}$, $l^{(1)}$, $l^{(2)}$, $l^{(1)}$. These parameters are defined through their contributions to the site displacement as given by equations (7.1a-7.1c) below. Their numerical values as listed in the Conventions 1996 have since been revised, and the new values presented in Table 7.2 are used here. These values pertain to the elastic Earth and anelasticity models referred to in Chapter 6.

The vector displacement $\Delta \vec{r}$ due to a tidal term of frequency $f$ is given by the following expressions that result from evaluation of the defining equation (7.2) of Mathews et al. (1995):

For a long-period tide of frequency $f$:

$$\Delta \vec{r}_f = \sqrt{\frac{5}{4\pi}} H_f \left\{ h(\phi) \left( \frac{3}{2} \sin^2 \phi - \frac{1}{2} \right) + \sqrt{\frac{4\pi}{5} h'} \right\} \cos \theta_f \hat{r}$$

$$+ 3l(\phi) \sin \phi \cos \phi \cos \theta_f \hat{n}$$

$$+ \cos \phi \left[ 3l^{(1)} \sin^2 \phi - \sqrt{\frac{24\pi}{5} l'} \right] \sin \theta_f \hat{e}. \hspace{1cm} (7.1a)$$

For a diurnal tide of frequency $f$:

$$\Delta \vec{r}_f = -\sqrt{\frac{5}{2\pi}} H_f \left\{ h(\phi)3 \sin \phi \cos \phi \sin(\theta_f + \lambda) \right\} \hat{r}$$

$$+ \left[ 3l(\phi) \cos 2\phi - 3l^{(1)} \sin^2 \phi + \sqrt{\frac{24\pi}{5} l'} \right] \sin(\theta_f + \lambda) \hat{n}$$

$$+ \left[ 3l(\phi) - \sqrt{\frac{24\pi}{5} l'} \right] \sin \phi - 3l^{(1)} \sin \phi \cos 2\phi \cos(\theta_f + \lambda) \hat{e}. \hspace{1cm} (7.1b)$$

For a semidiurnal tide of frequency $f$:

$$\Delta \vec{r}_f = \sqrt{\frac{5}{6\pi}} H_f \left\{ h(\phi)3 \cos^2 \phi \cos(\theta_f + 2\lambda) \right\} \hat{r}$$

$$- 6 \sin \phi \cos \phi \left[ l(\phi) + l^{(1)} \right] \cos(\theta_f + 2\lambda) \hat{n}$$

$$- 6 \cos \phi \left[ l(\phi) + l^{(1)} \sin^2 \phi \right] \sin(\theta_f + 2\lambda) \hat{e}. \hspace{1cm} (7.1c)$$

In the above expressions,

$$h(\phi) = h^{(0)} + h^{(2)}(3 \sin^2 \phi - 1)/2,$$

$$l(\phi) = l^{(0)} + l^{(2)}(3 \sin^2 \phi - 1)/2. \hspace{1cm} (7.2)$$
The convention used in defining the tidal amplitude $H_f$ is the one from Cartwright and Tayler (1971). To convert amplitudes defined according to other conventions that have been employed in recent more accurate tables, use the conversion factors given in Chapter 6, Table 6.8.

Equations (7.1) assume that the Love and Shida number parameters are all real. Generalization to the case of complex parameters is done simply by making the following replacements for the combinations $L \cos(\theta_f + m\lambda)$ and $L \sin(\theta_f + m\lambda)$, wherever they occur in those equations:

\[
\begin{align*}
L \cos(\theta_f + m\lambda) &\rightarrow LR \cos(\theta_f + m\lambda) - LI \sin(\theta_f + m\lambda), \\
L \sin(\theta_f + m\lambda) &\rightarrow LR \sin(\theta_f + m\lambda) + LI \cos(\theta_f + m\lambda),
\end{align*}
\]

where $L$ is a generic symbol for $h^{(0)}, h^{(2)}, h', l^{(0)}, l^{(1)}, l^{(2)}$, and $l'$, and where $LR$ and $LI$ stand for their respective real and imaginary parts.

The complex values of these 7 parameters are computed for the diurnal body tides from resonance formulae of the form given in Equation (6.9) of Chapter 6 using the values listed in Equation (6.10) of that chapter for the resonance frequencies $\sigma_\alpha$ and those listed in Table 7.1 for the coefficients $L_\alpha$ and $L_\alpha$ relating to each of the multiple $h$ and $l$ Love/Shida numbers. The manner in which $\sigma_\alpha$ and $L_\alpha$ were computed is explained in Chapter 6, where mention is also made of the models used for the elastic Earth and for mantle anelasticity. As was noted in that chapter, the frequency dependence of the ocean tide contributions to certain Earth parameters in the equations of motion for the wobbles has the effect of making the resonance formulae inexact. The difference between the exact and resonance formula values is included in the tabulated values of $h^{(0)}_{21}$ and $l^{(0)}_{21}$ in Table 7.2. (The only case where this difference makes a contribution above the cut-off in Table 7.3a is in the radial displacement due to the $\psi_1$ tide.) Also included in the values listed in Table 7.2 are the resonant ocean tidal loading corrections outlined in the next paragraph.

Site displacements caused by solid Earth deformations due to ocean tidal loading have been dealt with in the first section of this chapter. Constant nominal values were assumed for the load Love numbers in computing these. The values used for tides of degree 2 were $h_2^{(nom)} = -1.001$, $l_2^{(nom)} = 0.0295$, $k_2^{(nom)} = -0.3075$. Since resonances in the diurnal band also cause the values of the load Love numbers to vary, corrections need to be applied to the results of the first section. These corrections can be expressed in terms of effective ocean tide contributions $\delta h^{(OT)}$ and $\delta l^{(OT)}$ to the respective body tide Love numbers $h_{21}^{(OT)}$ and $l_{21}^{(OT)}$. $\delta h^{(OT)}$ and $\delta l^{(OT)}$ are given by expressions of the form (6.11) of Chapter 6, with appropriate replacements. They were computed using the same ocean tide admittances as in that chapter, and using the resonance parameters listed in Table 6.4 for the load Love numbers; they are included in the values listed in Table 7.2 under $h^{(OT)}_{21}$ and $l^{(OT)}_{21}$ for the diurnal tides.
Table 7.1: Parameters in the resonance formulae for the displacement Love numbers.

\[\begin{array}{cccccc}
\alpha & \text{Re} L_\alpha & \text{Im} L_\alpha & \text{Re} L_\alpha & \text{Im} L_\alpha \\
0 & .60671 \times 10^{-6} & -.2420 \times 10^{-2} & -.615 \times 10^{-3} & -.122 \times 10^{-4} \\
1 & -.15777 \times 10^{-5} & -.7630 \times 10^{-4} & .160 \times 10^{-5} & .116 \times 10^{-6} \\
2 & .18053 \times 10^{-3} & -.6292 \times 10^{-5} & .201 \times 10^{-6} & .279 \times 10^{-8} \\
3 & -.18616 \times 10^{-5} & .1379 \times 10^{-6} & -.329 \times 10^{-7} & -.217 \times 10^{-8} \\
\end{array}\]

The variation of \( h^{(0)}_{20} \) and \( l^{(0)}_{20} \) across the zonal tidal band, \((nm = 20)\), due to mantle anelasticity, is described by the formulae

\[\begin{align*}
    h^{(0)}_{20} &= 0.5998 - 9.96 \times 10^{-4} \left\{ \cot \frac{\alpha \pi}{2} \left[ 1 - \left( \frac{f_m}{f} \right)^\alpha \right] + i \left( \frac{f_m}{f} \right)^\alpha \right\}, \\
    l^{(0)}_{20} &= 0.0831 - 3.01 \times 10^{-4} \left\{ \cot \frac{\alpha \pi}{2} \left[ 1 - \left( \frac{f_m}{f} \right)^\alpha \right] + i \left( \frac{f_m}{f} \right)^\alpha \right\}
\end{align*}\]  

(7.4a)

(7.4b)

on the basis of the anelasticity model already referred to. Here \( f \) is the frequency of the zonal tidal constituent, \( f_m \) is the reference frequency equivalent to a period of 200 s, and \( \alpha = 0.15 \).

Table 7.2 lists the values of \( h^{(0)}, h^{(2)}, h', l^{(0)}, l^{(1)}, l^{(2)}, \) and \( l' \) for those tidal frequencies for which they are needed for use in the computational procedure described below. The tidal frequencies shown in the table are given in cycles per sidereal day (cpsd). Periods, in solar days, of the nutations associated with the diurnal tides are also shown.

Computation of the variations of station coordinates due to solid Earth tides, like that of geopotential variations, is done most efficiently by the use of a two-step procedure. The evaluations in the first step use the expression in the time domain for the full degree 2 tidal potential or for the parts that pertain to particular bands \((m = 0, 1, \alpha 2)\). Nominal values common to all the tidal constituents involved in the potential and to all stations are used for the Love and Shida numbers \( h_{2m} \) and \( l_{2m} \) in this step. They are chosen with reference to the values in Table 7.2 so as to minimize the computational effort needed in Step 2. Along with expressions for the dominant contributions from \( h^{(0)} \) and \( l^{(0)} \) to the tidal displacements, relatively small contributions from some of the other parameters are included in Step 1 for reasons of computational efficiency. The displacements caused by the degree 3 tides are also computed in the first step, using constant values for \( h_3 \) and \( l_3 \).
Corrections to the results of the first step are needed to take account of the frequency-dependent deviations of the Love and Shida numbers from their respective nominal values, and also to compute the out-of-phase contributions from the zonal tides. Computations of these corrections constitute Step 2. The total displacement due to the tidal potential is the sum of the displacements computed in Steps 1 and 2.

The full scheme of computations is outlined in the chart on page 103.

## CORRECTIONS FOR THE STATION TIDAL DISPLACEMENTS

### Step 1: Corrections to be computed in the time domain

#### in-phase for degree 2 and 3

- for degree 2 → eq (7.5)
  - for degree 2
    - Nominal values
      - $h_2 = h(0) + h(2)(3\sin^2 \phi - 1)/2$
      - $l_2 = l(0) + l(2)(3\sin^2 \phi - 1)/2$
      - $h(0) = 0.6078$, $h(2) = -0.0006$, $l(0) = 0.0847$, $l(2) = 0.0002$
  - for degree 3
    - Nominal values
    - $h_3 = 0.292$ and $l_3 = 0.015$

- for degree 3 → eq (7.6)
  - Nominal values
    - $h_3 = 0.292$ and $l_3 = 0.015$

#### out-of-phase for degree 2 only

- diurnal tides → eq (7.10)
  - Nominal values
  - $h^I = -0.0025$ and $l^I = -0.0007$
- semidiurnal tides → eq (7.11)
  - Nominal values
  - $l^{(1)} = 0.0012$

#### contribution from latitude dependence

- diurnal tides → eq (7.8)
  - Nominal values
  - $l^{(1)} = 0.0012$
- semidiurnal tides → eq (7.9)
  - Nominal values
  - $l^{(1)} = 0.0024$

### Step 2: Corrections to be computed in the frequency domain and to be added to the results of Step 1

#### in-phase for degree 2

- diurnal tides → eqs (7.12)
  - → Sum over all the components of Table 7.3a
- semidiurnal tides
  - → negligible

#### in-phase and out-of-phase for degree 2

- long-period tides → eqs (7.13)
  - → Sum over all the components of Table 7.3b

### Displacement due to degree 2 tides, with nominal values for $h_{2m}^{(0)}$ and $l_{2m}^{(0)}$

The first stage of the Step 1 calculations employs real nominal values $h_2$ and $l_2$ common to all the degree 2 tides for the Love and Shida numbers. It is found to be computationally most economical to choose these to be the values for the semidiurnal tides (which have very little intra-band variation). On using the nominal values, the displacement vector of the station due to the degree 2 tides is given by

$$\Delta \vec{r} = \sum_{j=2}^{3} \frac{GM_j R_j^5}{GM \cdot R_j^5} \left\{ h_2 \left(3(\hat{R}_j \cdot \hat{r})^2 - 1 \right) + 3l_2 (\hat{R}_j \cdot \hat{r}) \left[ \hat{R}_j - (\hat{R}_j \cdot \hat{r}) \hat{r} \right] \right\}, \quad (7.5)$$

where $h_{22}^{(0)}$ and $l_{22}^{(0)}$ of the semidiurnal tides are chosen as the nominal values $h_2$ and $l_2$. The out-of-phase displacements due to the imaginary parts of the Love numbers are dealt with separately below. In Equation (7.5),

103
Table 7.2: Displacement Love number parameters for degree 2 tides. Superscripts $R$ and $I$ identify the real and imaginary parts, respectively. Periods are given in solar days and frequencies in cpsd.

7.1 Models for conventional displacement of reference markers on the crust

\[ GM_j = \text{gravitational parameter for the Moon} \quad (j = 2) \]

or the Sun \((j = 3)\),

\[ GM_\oplus = \text{gravitational parameter for the Earth}, \]

\[ \hat{R}_j, R_j = \text{unit vector from the geocenter to Moon or Sun} \]

and the magnitude of that vector,

\[ R_e = \text{Earth’s equatorial radius}, \]

\[ \hat{r}, r = \text{unit vector from the geocenter to the station} \]

and the magnitude of that vector,

\[ h_2 = \text{nominal degree 2 Love number}, \]

\[ l_2 = \text{nominal degree 2 Shida number}. \]

Note that the part proportional to \(h_2\) gives the radial (not vertical) component of the tide-induced station displacement, and the terms in \(l_2\) represent the vector displacement perpendicular to the radial direction (and not in the horizontal plane).

The computation just described may be generalized to include the latitude dependence arising through \(h^{(2)}\) by simply adding \(h^{(2)} [\frac{3}{2} \sin^2 \phi - 1/2] \) to the constant nominal value given above, with \(h^{(2)} = -0.0006\). The addition of a similar term (with \(l^{(2)} = 0.0002\)) to the nominal value of \(l_2\) takes care of the corresponding contribution to the transverse displacement. The resulting incremental displacements are small, not exceeding 0.4 mm radially and 0.2 mm in the transverse direction.

**Displacement due to degree 3 tides**

The Love numbers of the degree 3 tides may be taken as real and constant in computations to the degree of accuracy aimed at here. The displacement vector due to these tides is then given by

\[
\Delta \vec{r} = \sum_{j=2}^{3} \frac{GM_j R_j^5}{GM_\oplus R_\oplus^4} \left\{ h_3 \left( \frac{5}{2} (\hat{R}_j \cdot \hat{r})^3 - \frac{3}{2} (\hat{R}_j \cdot \hat{r}) \right) + l_3 \left( \frac{15}{2} (\hat{R}_j \cdot \hat{r})^2 - \frac{3}{2} \right) \left[ \hat{R}_j - (\hat{R}_j \cdot \hat{r}) \hat{r} \right] \right\},
\]

\[(7.6)\]

Only the Moon’s contribution \((j = 2)\) needs to be computed, the term due to the Sun being negligible. The transverse part of the displacement \((7.6)\) does not exceed 0.2 mm, but the radial displacement can reach 1.7 mm.

**Contributions to the transverse displacement due to the \(l^{(1)}\) term**

The imaginary part of \(l^{(1)}\) is negligible, as is the intra-band variation of Re \(l^{(1)}\); and \(l^{(1)}\) is effectively zero in the zonal band.

In the expressions given below, and elsewhere in this chapter,

\[ \Phi_j = \text{body fixed geocentric latitude of Moon or Sun}, \]

\[ \lambda_j = \text{body fixed east longitude (from Greenwich) of Moon or Sun}. \]

The following formulae may be employed when the use of Cartesian coordinates \(X_j, Y_j, Z_j\) of the body relative to the terrestrial reference frame is preferred:

\[
P_2^0(\sin \Phi_j) = \frac{1}{R_j^3} \left( \frac{5}{2} Z_j^2 - \frac{1}{2} R_j^2 \right),
\]

\[(7.7a)\]

\[
P_2^1(\sin \Phi_j) \cos \lambda_j = \frac{3 X_j Z_j}{R_j^4},
\]

\[
P_2^1(\sin \Phi_j) \sin \lambda_j = \frac{3 Y_j Z_j}{R_j^4},
\]

\[(7.7b)\]

\[
P_2^2(\sin \Phi_j) \cos 2 \lambda_j = \frac{3}{R_j^7} (X_j^2 - Y_j^2),
\]

\[
P_2^2(\sin \Phi_j) \sin 2 \lambda_j = \frac{6}{R_j^7} X_j Y_j.
\]

\[(7.7c)\]

Contribution from the diurnal band (with \(l^{(1)} = 0.0012\)):
\[ \delta \vec{r} = -l^{(1)} \sin \phi \sum_{j=2}^{3} \frac{GM_{i} R_{i}^{4}}{GM_{\oplus} R_{\oplus}^{4}} P_{2}^{l}(\sin \Phi_{j}) [\sin \phi \cos(\lambda - \lambda_{j}) \hat{n} - \cos \phi \sin(\lambda - \lambda_{j}) \hat{e}] . \] (7.8)

Contribution from the semi-diurnal band (with \( l^{(1)} = 0.0024 \)):

\[ \delta \vec{t} = -\frac{1}{2} l^{(1)} \sin \phi \cos \phi \sum_{j=2}^{3} \frac{GM_{i} R_{i}^{4}}{GM_{\oplus} R_{\oplus}^{4}} P_{3}^{l}(\sin \Phi_{j}) [\cos(2(\lambda - \lambda_{j}) \hat{n} + \sin \phi \sin(2(\lambda - \lambda_{j}) \hat{e}) . \] (7.9)

The contributions of the \( l^{(1)} \) term to the transverse displacement caused by the diurnal and semi-diurnal tides could be up to 0.8 mm and 1.0 mm, respectively.

Out-of-phase contributions from the imaginary parts of \( h_{2m}^{(0)} \) and \( \ell_{2m}^{(0)} \):

In the following, \( h^{l} \) and \( l^{l} \) stand for the imaginary parts of \( h_{2m}^{(0)} \) and \( \ell_{2m}^{(0)} \).

Contributions \( \delta r \) to radial and \( \delta \vec{t} \) to transverse displacements from diurnal tides (with \( h^{l} = -0.0025, \ell^{l} = -0.0007 \)):

\[ \delta r = -\frac{3}{4} h^{l} \sum_{j=2}^{3} \frac{GM_{i} R_{i}^{4}}{GM_{\oplus} R_{\oplus}^{4}} \sin 2\Phi_{j} \sin 2\phi \sin(\lambda - \lambda_{j}) , \] (7.10a)

\[ \delta \vec{t} = -\frac{3}{2} \ell^{l} \sum_{j=2}^{3} \frac{GM_{i} R_{i}^{4}}{GM_{\oplus} R_{\oplus}^{4}} \sin 2\Phi_{j} [\cos 2\phi \sin(\lambda - \lambda_{j}) \hat{n} + \sin \phi \cos(\lambda - \lambda_{j}) \hat{e}] . \] (7.10b)

Contributions from semi-diurnal tides (with \( h^{l} = -0.0022, \ell^{l} = -0.0007 \)):

\[ \delta r = -\frac{3}{4} h^{l} \sum_{j=2}^{3} \frac{GM_{i} R_{i}^{4}}{GM_{\oplus} R_{\oplus}^{4}} \cos^{2} \Phi_{j} \cos^{2} \phi \sin 2(\lambda - \lambda_{j}) , \] (7.11a)

\[ \delta \vec{t} = \frac{3}{4} \ell^{l} \sum_{j=2}^{3} \frac{GM_{i} R_{i}^{4}}{GM_{\oplus} R_{\oplus}^{4}} \cos^{2} \Phi_{j} [\sin 2\phi \sin 2(\lambda - \lambda_{j}) \hat{n} - 2 \cos \phi \cos 2(\lambda - \lambda_{j}) \hat{e}] . \] (7.11b)

The out-of-phase contribution from the zonal tides has no closed expression in the time domain.

Computations of Step 2 take account of the intra-band variation of \( h_{2m}^{(0)} \) and \( \ell_{2m}^{(0)} \). Variations of the imaginary parts are negligible except as stated below (see Table 7.3a). For the zonal tides, however, the contributions from the imaginary part have to be computed in Step 2.

Correction for frequency dependence of the Love and Shida numbers

(a) Contributions from the diurnal band

Corrections, which include both in-phase (ip) and out-of-phase (op) parts, to the radial and transverse station displacements \( \delta r \) and \( \delta \vec{t} \) due to a diurnal tidal term of frequency \( f \) are obtainable from Equation (7.1b):

\[ \delta r = [\delta R_{f}^{(ip)} \sin(\theta_{f} + \lambda) + \delta R_{f}^{(op)} \cos(\theta_{f} + \lambda)] \sin 2\phi , \] (7.12a)

\[ \delta \vec{t} = [\delta T_{f}^{(ip)} \cos(\theta_{f} + \lambda) - \delta T_{f}^{(op)} \sin(\theta_{f} + \lambda)] \sin \phi \hat{e} + [\delta T_{f}^{(ip)} \sin(\theta_{f} + \lambda) + \delta T_{f}^{(op)} \cos(\theta_{f} + \lambda)] \cos 2\phi \hat{n} , \] (7.12b)
where

\[
\begin{pmatrix}
\delta R_f^{(ip)} \\
\delta R_f^{(op)}
\end{pmatrix}
= -\frac{3}{2} \sqrt{\frac{5}{2\pi}} H_f \begin{pmatrix}
\delta h_f^R \\
\delta h_f^I
\end{pmatrix},
\]

\[\begin{pmatrix}
\delta T_f^{(ip)} \\
\delta T_f^{(op)}
\end{pmatrix}
= -3 \sqrt{\frac{5}{2\pi}} H_f \begin{pmatrix}
\delta l_f^R \\
\delta l_f^I
\end{pmatrix},
\]

(7.12c)

and

\[\delta h_f^R \text{ and } \delta h_f^I \text{ are the differences of } h^{(0)R} \text{ and } h^{(0)I} \text{ at frequency } f \text{ from the nominal values } h_2 \text{ and } h' \text{ used in Equations (7.5) and (7.10a), respectively,}
\]

\[\delta l_f^R \text{ and } \delta l_f^I \text{ are the differences of } l^{(0)R} \text{ and } l^{(0)I} \text{ at frequency } f \text{ from the nominal values } l_2 \text{ and } l' \text{ used in Equations (7.5) and (7.10b), respectively.}
\]

(b) Contributions from the long-period band.

Corrections \(\delta r\) and \(\delta \vec{t}\) due to a zonal tidal term of frequency \(f\) include both \(ip\) and \(op\) parts. From Equations (7.1a) and (7.3) one finds

\[
\delta r = \frac{3}{2} \sin^2 \phi - \frac{1}{2} \left( \delta R_f^{(ip)} \cos \theta_f + \delta R_f^{(op)} \sin \theta_f \right),
\]

(7.13a)

\[
\delta \vec{t} = \left( \delta T_f^{(ip)} \cos \theta_f + \delta T_f^{(op)} \sin \theta_f \right) \sin 2\phi \hat{n},
\]

(7.13b)

where

\[
\begin{pmatrix}
\delta R_f^{(ip)} \\
\delta R_f^{(op)}
\end{pmatrix}
= \sqrt{\frac{5}{2\pi}} H_f \begin{pmatrix}
\delta h_f^R \\
-\delta h_f^I
\end{pmatrix},
\]

(7.13c)

\[
\begin{pmatrix}
\delta T_f^{(ip)} \\
\delta T_f^{(op)}
\end{pmatrix}
= \frac{3}{2} \sqrt{\frac{5}{2\pi}} H_f \begin{pmatrix}
\delta l_f^R \\
-\delta l_f^I
\end{pmatrix}.
\]
Table 7.3b: Corrections due to the frequency dependence of Love and Shida numbers for zonal tides.

Units: mm. All terms with radial correction \( \geq 0.05 \) mm are shown. Nominal values are \( h = 0.6078 \) and \( l = 0.0847 \). Frequencies are given in degrees per hour.

</table>

Values of \( \Delta R_f \) and \( \Delta T_f \) listed in Table 7.3a and 7.3b are for the constituents that must be taken into account to ensure an accuracy of 1 mm.

A Fortran program (DEHANTTIDEINEL.F) for computing the steps 1 and 2 corrections is available at ftp://tai.bipm.org/iers/conv2010/chapter7/

7.1.1.2 Permanent deformation

The tidal model described above in principle contains a time-independent part so that the coordinates obtained by taking into account this model in the analysis will be “conventional tide free” values. (Note that they do not correspond to what would be observed in the absence of tidal perturbation. See the discussion in Chapter 1.) This section allows a user to compute “mean tide” coordinates from “conventional tide free” coordinates.

Specifically, the degree 2 zonal tide generating potential includes a spectral component of zero frequency and amplitude \( H_0 = -0.31460 \) m, and its effect enters the tidal displacement model through the time-independent component of expression (7.5). Evaluation of this component may be done using Equations (7.1a) and (7.2) with \( H_f = H_0, \theta_f = 0 \), and with the same nominal values for the Love number parameters as were used in Step 1: \( h_2 = 0.6078, l_2 = 0.0847 \) along with \( K(2) = -0.0006 \) and \( l(2) = 0.0002 \). One finds the radial component of the permanent displacement according to (7.5) to be

\[
[-0.1206 + 0.0001P_2(\sin \phi)] P_2(\sin \phi) \quad (7.14a)
\]

in meters, and the transverse component to be

\[
[-0.0252 - 0.0001P_2(\sin \phi)] \sin 2\phi \quad (7.14b)
\]

in meters northwards, where \( P_2(\sin \phi) = (3\sin^2 \phi - 1)/2 \).

These are the components of the vector to be added to the “conventional tide free” computed tide-corrected position to obtain the “mean tide” position. The radial component of this restitution to obtain the “mean tide” value amounts to about \(-12\) cm at the poles and about \(+6\) cm at the equator.

7.1.2 Local site displacement due to ocean loading

Ocean tides cause a temporal variation of the ocean mass distribution and the associated load on the crust and produce time-varying deformations of the Earth that can reach 100 mm. The modeling of the associated site displacement is dealt with in this section.

Note on motion of the center of mass of the solid Earth

When the solid Earth together with the fluid masses are considered as a system without any external forces acting upon it, the position of the common center of mass remains fixed in space. When a phenomenon, such as the ocean tides,
7.1 Models for conventional displacement of reference markers on the crust

causes displacements of fluid masses, the center of mass of the fluid masses moves periodically and must be compensated by an opposite motion of the center of mass of the solid Earth. The stations, being fixed to the solid Earth, are subject to this counter-motion.

For observing techniques that rely upon the dynamical motion of satellites, which respond to the center of mass of the total Earth system, the modeled motions of crust-fixed stations should include the “geocenter motion” contributions that counterbalance the effects of the fluid components. For other observing techniques, such as VLBI, neglect of geocenter motion should have no observable consequences.

Models for ocean tidal loading

The tide generating potential due to the gravitational attraction of the Moon and the Sun can be described by an expansion into a set of tidal harmonics (e.g. Hartmann and Wenzel, 1995; Tamura, 1987; Cartwright and Tayler, 1971; Cartwright and Edden, 1973). The response of the oceans, unlike for the solid Earth, is strongly dependent on local and regional conditions that affect fluid flow. Closed-form analytical expressions are not adequate to describe the ocean tidal response globally. Instead, gridded formulations are needed. Table 7.4 lists the leading global ocean tidal models that have been developed since Schwiderski and Szeto (1981). Most modern models assimilate sea surface height measurements made by altimetry satellites.

The crustal loading at a particular location due to a given tidal harmonic is computed by integrating the tide height with a weighting function (Green’s function, see Farrell, 1972), carrying the integration over all the ocean masses. The total loading may be obtained by summing the effect of all harmonics. In practice, the three-dimensional site displacements due to ocean tidal loading are computed using the following scheme. Let $\Delta c$ denote a displacement component (radial, west, south) at a particular site at time $t$. $\Delta c$ is obtained as

$$\Delta c = \sum_j A_{cj} \cos(\chi_j(t) - \phi_{cj}),$$

where the summation is carried out for a set of tidal constituents. The amplitudes $A_{cj}$ and phases $\phi_{cj}$ describe the loading response for the chosen site. The astronomical argument $\chi_j(t)$ for the 11 main tides can be computed with the subroutine ARG2.F, which can be obtained at <1>.

Conventionally, only a discrete set of harmonics in the long-period ($m = 0$), diurnal ($m = 1$) and semidiurnal ($m = 2$) bands are usually considered explicitly. The 11 main tides considered are the semidiurnal waves $M_2, S_2, N_2, K_2$, the diurnal waves $K_1, O_1, P_1, Q_1$, and the long-period waves $M_f, M_m, S_\omega$. The site-dependent amplitudes $A_{cj}$ and phases $\phi_{cj}$ for these 11 tides are obtained as described in the next sub-section. Amplitudes and phases for other tidal constituents can be obtained from those of the 11 main tides by a variety of approximation schemes. For instance, if one wishes to include the effect of sidelobes of the main tides generated by modulation with the 18.6-year lunar node, then suitable adjustments in the 11 amplitudes and phases can be applied so that

$$\Delta c = \sum_{k=1}^{11} f_k A_{ck} \cos(\chi_k(t) + u_k - \phi_{ck}),$$

where $f_k$ and $u_k$ depend on the longitude of the lunar node. See Scherneck (1999) for the expression of these arguments.

In more complete methods, the lesser tides are handled by interpolation of the admittances using some full tidal potential development (e.g. Hartmann and Wenzel, 1995). One of these methods has been chosen as the conventional IERS method, and has been implemented in a subroutine that is recommended as a conventional computation of the loading displacement (see sub-section “Conventional routine to compute the ocean loading displacement” below).
Note that complete neglect of the minor tides and nodal modulations, using (7.15) with only the 11 main tides, is not recommended and may lead to errors of several mm, up to 5 mm rms at high latitudes (Hugentobler, 2006).

Additional contributions to ocean-induced displacement arise from the frequency dependence of the load Love numbers due to the Nearly Diurnal Free Wobble in the diurnal tidal band. The effect of this dependence has been taken into account, following Wahr and Saso (1981), by incrementing the body tide Love numbers as explained in Section 7.1.1.

**Site-dependent tidal coefficients**

For a given site, the amplitudes $A_{c,j}$ and phases $\phi_{c,j}$, $1 \leq j \leq 11$, for the 11 main tides may be obtained electronically from the ocean loading service site at <http://froste.oso.chalmers.se/loading>; see Scherneck (1991). They are provided in either the so-called BLQ format or in the HARPOS format. An example for the BLQ format is given in Table 7.5. Note that tangential displacements are to be taken positive in west and south directions. The service allows coefficients to be computed selectably from any of eighteen ocean tide models; see Table 7.4.

The accuracy of the ocean tide loading values depends on the errors in the ocean tide models, the errors in the Green’s function, the coastline representation and the numerical scheme of the loading computation itself. To have a correct representation of the water areas one normally uses a high resolution coastline of around 600 m to 2 km. Note that still some problems exist near Antarctica where one should use the real land coastline instead of the ice shelf edges. Different elastic Earth models produce different Green’s functions but their differences are small, less than 2%. Most numerical schemes to compute the loading are good to about 2-5%. Currently, the largest contributor to the uncertainty in the loading value are the errors in the ocean tide models. Therefore it is recommended to use the most recent ocean tide models (TPXO7.2, see <http://volkov.oce.orst.edu/tides/TPXO7.2.html> for a solution derived using tide gauge and TOPEX/Poseidon data; FES2004 for a hydrodynamic solution with altimetry data). However, older models might sometimes be preferred for internal consistency. Since many space geodesy stations are inland or near coasts, the accuracy of the tide models in the shelf areas is more crucial than in the open sea. Load convolution adopts land-sea masking according to the high resolution coastlines dataset included in the Generic Mapping Tools (GMT, Wessel and Smith, 1998). Ocean tide mass budgets have been constrained using a uniform co-oscillation oceanic layer. The integrating loading kernel employs a disk-generating Green’s function method (Farrell, 1972; Zschau, 1983; Scherneck, 1990).

When generating tables of amplitudes and phases using the ocean loading service, one has to answer the question “Do you want to correct your loading values for the [geocenter] motion?”

Answering “No” means that the coefficients do not include the large-scale effect of the geocenter motion caused by the ocean tide. This is appropriate for station coordinates given in a “crust-fixed” frame that is not sensitive to the Earth’s center of mass.

Answering “Yes” means that the coefficients include the large-scale effect of the geocenter motion caused by the ocean tide. This is consistent with data analyses that realize a near-instantaneous “center of mass” frame using observations of satellite dynamics.

**Conventional routine to compute the ocean loading displacement**

D. Agnew has provided a Fortran program (HARDISP.F) to compute the ocean tide loading displacements for a site, given the amplitudes $A_{c,j}$ and phases $\phi_{c,j}$, $1 \leq j \leq 11$, as generated by the Bos-Scherneck website (in BLQ format, see above). The implementation considers a total of 342 constituent tides whose amplitudes and phases are found by spline interpolation of the tidal admittances based on the 11 main tides. Tests have been carried out showing that differences with an

Earlier version of HARDISP.F with 141 constituent tides are of order 0.1 mm rms. Comparisons with the ETERNA software of Wenzel (1996) have been carried out by M. Bos (2005), who concludes that the routine is precise to about 1%. Uncertainties in the ocean models are generally larger. The code for the routine can be obtained at $<^3>$.

Center of mass correction

If necessary, the crust-frame translation (geocenter motion) due to the ocean tidal mass, $dX(t), dY(t),$ and $dZ(t)$, may be computed according to the method given...
by Scherneck at
\[ dX(t) = \sum_{k=1}^{11} X_{in}(k) \cos(\chi_k(t)) + X_{cr}(k) \sin(\chi_k(t)) \]

where the in-phase \((in)\) and cross-phase \((cr)\) amplitudes (in meters) are tabulated for the various ocean models. Similarly for \(dY(t)\) and \(dZ(t)\). This correction should be applied, for instance, in the transformation of GPS orbits from the center-of-mass to the crust-fixed frame expected in the sp3 orbit format.

\[ X_{\text{crust-fixed}} = X_{\text{center-of-mass}} - dX, \]

i.e. the translation vector should be substracted when going from center-of-mass to sp3.

### 7.1.3 \(S_1-S_2\) atmospheric pressure loading

The diurnal heating of the atmosphere causes surface pressure oscillations at diurnal \(S_1\), semidiurnal \(S_2\), and higher harmonics. These “atmospheric tides” induce periodic motions of the Earth’s surface (Petrov and Boy, 2004). Previously, the \(S_1\) and \(S_2\) loading effects have not been included in the station motion model. Figure 7.1 shows the amplitude and phase of the predicted vertical deformation of the \(S_1\) and \(S_2\) tides derived from the model of Ray and Ponte (2003) using elastic Green’s functions (Farrell, 1972) in the center of mass of Earth + fluid masses (CM) frame. Horizontal deformations (not shown) are a factor of 10 smaller in amplitude. The amplitude of the vertical deformation is equal to that of some ocean tide loading effects and should, therefore, be considered in the station motion model. Being close to the orbital period of the GPS satellites, modeling of the \(S_2\) effect is especially important for this technique in order to minimize aliasing (Tregoning and Watson, 2009).

The conventional recommendation is to calculate the station displacement using the Ray and Ponte (2003) \(S_2\) and \(S_1\) tidal model, hereafter referred to as RP03.

**Tidal model**

The \(S_1\) and \(S_2\) RP03 tidal model is derived from the European Centre for Medium-Range Weather Forecasts (ECMWF) operational global surface pressure fields, using a procedure outlined by van den Dool et al. (1997). The \(S_2\) model has been tested by comparison against 428 barometer stations (Ray and Ponte, 2003). It is expected that National Centers for Environmental Prediction (NCEP) operational data provide equivalent results (van den Dool, 2004). Similar comparisons were found for the \(S_1\) models, although those tests were far less extensive. The barometer stations have also revealed small phase errors in the derived tidal fields. The origin of these errors is not understood, but the models can be corrected \textit{a posteriori}. The RP03 phases have been adjusted by 20 minutes to correct for this error.

**Calculation of loading effects**

We use elastic Green’s functions (Farrell, 1972) derived in the various reference frames to generate the predicted in-phase and out-of-phase surface displacement from RP03. The spatial resolution of the input surface pressure grid is 1.125°.

Elastic Green’s functions (versus frequency-dependent Green’s functions) are sufficient for this computation. By considering changes in viscoelasticity, Francis and Mazzega (1990) demonstrated that the amplitude of the \(M_2\) ocean tidal radial surface displacement can vary by 1.5% and the phase by 3%, \textit{i.e.} a negligible amount in comparison to uncertainties in the ocean tide model itself. A 1.5% effect on the \(S_2\) radial displacement is 0.05 mm in amplitude which is certainly less than the uncertainty in the \(S_1\) and \(S_2\) pressure models and can be ignored.

\[^4\]http://froste.oso.chalmers.se/loading/cmc.html
In addition, differences in predicted displacements derived from different Green’s functions are on the order of 0.1 mm rms, so it seems unnecessary to generate corrections using Green’s functions derived for different Earth models. The three-dimensional surface displacements are determined by assuming that the oceans respond as the solid Earth to the load, i.e. no inverted barometer. At these frequencies, the ocean does not have time to achieve equilibrium. Furthermore, it should be noted that the ocean’s response to these atmospheric tides is already modeled separately through the site displacements due to ocean tidal loading described in Section 7.1.2.

The phase convention follows that of RP03. At any geographic location, at any time, the tidal deformation, expressed in terms of up, east and north components, is the sum of \( d(u, e, n)_{S_1} \) and \( d(u, e, n)_{S_2} \) defined as

\[
d(u, e, n)_{S_1} = A_{d1}(u, e, n) \ast \cos(\omega_1 T) + B_{d1}(u, e, n) \ast \sin(\omega_1 T) \tag{7.19a}
\]

\[
d(u, e, n)_{S_2} = A_{d2}(u, e, n) \ast \cos(\omega_2 T) + B_{d2}(u, e, n) \ast \sin(\omega_2 T), \tag{7.19b}
\]
where $A_{d1}, B_{d1}, A_{d2}, B_{d2}$ are the surface displacement coefficients expressed in the same length unit as the deformation components, $T$ is UT1 in days and $\omega_1$ and $\omega_2$ are the frequencies of the $S_1$ and $S_2$ atmospheric tides, e.g. $\omega_1 = 1\text{ cycle/day}$ and $\omega_2 = 2\text{ cycles/day}$.

The surface displacement coefficients $A_{d1}, B_{d1}, A_{d2}, B_{d2}$ are determined for each site by performing a global convolution sum of the Green’s functions with the $\cos S_1, \sin S_1, \cos S_2, \sin S_2$ pressure mass coefficients. Gridded values of the three-dimensional predicted surface displacements from the RP03 model may be found at \[5\]. Corrections for the vertical surface displacement are usually sufficient, whereas estimates of horizontal effects are provided for completeness. The grids are provided for the two fundamental reference frames used for geodetic data analysis: center of solid Earth (CE) and center of mass of Earth + atmosphere + ocean + water storage (CM). In most applications, e.g. corrections of satellite-based techniques at the observation level, the CM frame is most appropriate. A description of the grid indexing as well as a program `grdintrp.f` for interpolating the grids are also available at \[5\].

**Center of mass correction**

As with ocean tidal loading (see preceding section), it may be necessary to compute the crust-frame translation (geocenter motion) due to the atmospheric tidal mass, $dX(t), dY(t),$ and $dZ(t)$ may be computed according to the method given by Scherneck at \[6\], e.g. for $dX(t)$ as

$$dX(t) = A_1 \cos(\omega_1 T) + B_1 \sin(\omega_1 T) + A_2 \cos(\omega_2 T) + B_2 \sin(\omega_2 T)$$  \hspace{1cm} (7.20)

where, as above, $\omega_1 = 1\text{ cycle/day}$ and $\omega_2 = 2\text{ cycles/day}$ and $A_1, B_1, A_2, B_2$ are the amplitudes of the in-phase and out-of-phase components of the atmospheric tides (in meters) and are given in Table 7.6 and in the file `com.dat` available at \[5\]. As with ocean tidal loading (see preceding section), this correction should be applied in transforming GPS orbits from the center-of-mass to the crust-fixed frame expected in the sp3 orbit format.

**7.1.4 Rotational deformation due to polar motion**

The variation of station coordinates caused by the pole tide can amount to a couple of centimeters and needs to be taken into account.

Let us choose $\hat{x}, \hat{y}$ and $\hat{z}$ as a terrestrial system of reference. The $\hat{z}$-axis is oriented along the Earth’s mean rotation axis, the $\hat{x}$-axis points in the direction of the adopted origin of longitude and the $\hat{y}$-axis is orthogonal to the $\hat{x}$- and $\hat{z}$- axes and in the plane of the 90° E meridian.

The centrifugal potential caused by the Earth’s rotation is

$$V = \frac{1}{2} \left( r^2 |\vec{\Omega}|^2 - (\vec{r} \cdot \vec{\Omega})^2 \right),$$  \hspace{1cm} (7.21)

where $\vec{\Omega} = \Omega (m_1 \hat{x} + m_2 \hat{y} + (1 + m_3) \hat{z})$. $\Omega$ is the mean angular velocity of the Earth’s rotation; $m_1, m_2$ describe the time-dependent offset of the instantaneous rotation pole from the mean, and $m_3$, the fractional variation in the rotation rate; $r$ is the geocentric distance to the station.

\[5\]http://geophy.uni.lu/ggfc-atmosphere/tide-loading-calculator.html

\[6\]http://froste.oso.chalmers.se/loading/cmc.html
Neglecting the variations in $m_3$ which induce displacements that are below the mm level, the $m_1$ and $m_2$ terms give a first order perturbation in the potential $V$ (Wahr, 1985)

$$
\Delta V(r, \theta, \lambda) = -\frac{\Omega^2 r^2}{2} \sin 2\theta (m_1 \cos \lambda + m_2 \sin \lambda).
$$

(7.22)

The radial displacement $S_r$ and the horizontal displacements $S_\theta$ and $S_\lambda$ (positive upwards, south and east, respectively, in a horizon system at the station) due to $\Delta V$ are obtained using the formulation of tidal Love numbers $h_2$ and $\ell_2$ (Munk and MacDonald, 1960):

$$
S_r = h_2 \frac{\Delta V}{g}, \quad S_\theta = \frac{\ell_2}{g} \partial_\theta \Delta V, \quad S_\lambda = \frac{\ell_2}{g} \frac{1}{\sin \theta} \partial_\lambda \Delta V.
$$

(7.23)

The position of the Earth’s mean rotation pole has a secular variation, and its coordinates in the Terrestrial Reference Frame discussed in Chapter 4 are given, in terms of the polar motion variables $(x_p, y_p)$ defined in Chapter 5, by appropriate running averages $\bar{x}_p$ and $-\bar{y}_p$. Then

$$
m_1 = x_p - \bar{x}_p, \quad m_2 = -(y_p - \bar{y}_p).
$$

(7.24)

For the most accurate results, an estimate of the wander of the mean pole should be used, that represents the secular variation to within about 10 mas. This ensures that the geopotential field is aligned to the long term mean pole (see Section 6.1) within the present geodetic accuracy. This is no longer the case (Ries, 2010) with the conventional mean pole of the IERS Conventions (2003) which is to be replaced with the model given below. In the future, the IERS conventional mean pole will be revised as needed with sufficient advance notice. The present version (2010) of the conventional mean pole is composed of a cubic model valid over the period 1976.0–2010.0 and a linear model for extrapolation after 2010.0, ensuring continuity and derivability at 2010.0. The cubic model was derived by the IERS Earth Orientation Centre from a fit over the period 1976.0–2010.0 of the data in <7>. This data itself was obtained (Gambis, 2010) by filtering periodic terms in the EOP(IERS) C01 series <8> with an X11 Census process (Shiskin et al., 1967). The IERS (2010) mean pole model reads

$$
\bar{x}_p(t) = \sum_{i=0}^{3} (t - t_0)^i \times \bar{x}_p^i, \quad \bar{y}_p(t) = \sum_{i=0}^{3} (t - t_0)^i \times \bar{y}_p^i,
$$

(7.25)

where $t_0$ is 2000.0 <8> and the coefficients $\bar{x}_p^i$ and $\bar{y}_p^i$ are given in Table 7.7.

Table 7.7: Coefficients of the IERS (2010) mean pole model

Note that the original data used to generate the linear model used Besselian epochs. Thus, strictly speaking, the time argument $t$ in (7.25) is also a Besselian epoch. However, for all practical purposes, a Julian epoch may be used for $t$. 

<ftp://tai.bipm.org/iers/conv2010/chapter7/annual.pole>

<ftp://hpiers.obspm.fr/iers/eop/eopc01>

9Note that the original data used to generate the linear model used Besselian epochs. Thus, strictly speaking, the time argument $t$ in (7.25) is also a Besselian epoch. However, for all practical purposes, a Julian epoch may be used for $t$. 

115
Using Love number values appropriate to the frequency of the pole tide \((h_2 = 0.6207, l_2 = 0.0836)\) and \(r = a = 6.378 \times 10^6\) m, one finds

\[
\begin{align*}
S_r &= -33 \sin 2\theta \left( m_1 \cos \lambda + m_2 \sin \lambda \right) \text{ inmm}, \\
S_\theta &= -9 \cos 2\theta \left( m_1 \cos \lambda + m_2 \sin \lambda \right) \text{ inmm}, \\
S_\lambda &= 9 \cos \theta \left( m_1 \sin \lambda - m_2 \cos \lambda \right) \text{ inmm},
\end{align*}
\]

with \(m_1\) and \(m_2\) given in arcseconds. Note that the values of the Love numbers include the anelastic contributions to the real part, which induce a contribution to the displacement of order 1 mm, but do not include the contributions to the imaginary part, whose effects are about 5 times smaller. Taking into account that \(m_1\) and \(m_2\) vary, at most, by 0.8 as, the maximum radial displacement is approximately 25 mm, and the maximum horizontal displacement is about 7 mm. If \(X, Y,\) and \(Z\) are Cartesian coordinates of a station in a right-handed equatorial coordinate system, the changes in them due to polar motion are (note that the order of components is different in Equations (7.26) and (7.27))

\[
[dX, dY, dZ]^T = R^T[S_\theta, S_\lambda, S_r]^T, \tag{7.27}
\]

where

\[
R = \begin{pmatrix}
\cos \theta \cos \lambda & \cos \theta \sin \lambda & -\sin \theta \\
-\sin \lambda & \cos \lambda & 0 \\
\sin \theta \cos \lambda & \sin \theta \sin \lambda & \cos \theta
\end{pmatrix}. \tag{7.28}
\]

### 7.1.5 Ocean pole tide loading

The ocean pole tide is generated by the centrifugal effect of polar motion on the oceans. This centrifugal effect is defined in Equation (6.10) of Section 6.2. Polar motion is dominated by the 14-month Chandler wobble and annual variations. At these long periods, the ocean pole tide is expected to have an equilibrium response, where the displaced ocean surface is in equilibrium with the forcing equipotential surface.

Desai (2002) presents a self-consistent equilibrium model of the ocean pole tide. This model accounts for continental boundaries, mass conservation over the oceans, self-gravitation, and loading of the ocean floor. Using this model, the load of the ocean pole tide produces the following deformation vector at any point on the surface of the Earth with latitude \(\phi\) and longitude \(\lambda\). The load deformation vector is expressed here in terms of radial, north and east components, \(u_r, u_n,\) and \(u_e,\) respectively, and is a function of the wobble parameters \((m_1, m_2)\).

\[
\begin{bmatrix}
u_r(\phi, \lambda) \\
u_n(\phi, \lambda) \\
u_e(\phi, \lambda)
\end{bmatrix} = K \begin{bmatrix}
u_r^P(\phi, \lambda) \\
u_n^P(\phi, \lambda) \\
u_e^P(\phi, \lambda)
\end{bmatrix} + (m_1 \gamma_2^R - m_2 \gamma_2^I) \begin{bmatrix}
u_r(\phi, \lambda) \\
u_n(\phi, \lambda) \\
u_e(\phi, \lambda)
\end{bmatrix} \tag{7.29}
\]

where

\[
K = \frac{4\pi G a_E \rho_w H_p}{3g_e}
\]

and

\[
H_p = \left( \frac{8\pi}{15} \right)^{1/2} \frac{\Omega^2 a_E^4}{GM}
\]

and

\[
\Omega, a_E, GM, g_e, \text{ and } G \text{ are defined in Chapter 1,}
\]

\[
\rho_w = \text{density of sea water} = 1025 \text{ kg m}^{-3},
\]

\[
\gamma = (1 + k_2 - h_2) = \gamma_2^R + i\gamma_2^I = 0.6870 + 0.0036i \text{ (Values of } k_2 \text{ and } h_2 \text{ appropriate for the pole tide are as given in Sections 6.2 and 7.1.4),}
\]
7.1 Models for conventional displacement of reference markers on the crust

Figure 7.2: Loading from ocean pole tide: Amplitude as a function of the amplitude of wobble variable.

\((m_1, m_2)\) are the wobble parameters. Refer to Section 7.1.4 for the relationship between the wobble variables \((m_1, m_2)\) and the polar motion variables \((x_p, y_p)\).

\(u^r_{m_1}(\phi, \lambda), u^b_{m_1}(\phi, \lambda), u^l_{m_1}(\phi, \lambda)\) are the real part of the ocean pole load tide coefficients.

\(u^i_{m_1}(\phi, \lambda), u^j_{m_1}(\phi, \lambda), u^k_{m_1}(\phi, \lambda)\) are the imaginary part of the ocean pole load tide coefficients.
coefficients.
Maps of the required ocean pole load tide coefficients are available on an equally spaced 0.5 by 0.5 degree global grid at \(<10^7\). These coefficients provide the surface deformations with respect to the instantaneous center of mass of the deformed Earth including the mass of the loading ocean pole tide.

The amplitude of this loading deformation is shown in Figure 7.2 in mm per arc-second as a function of the amplitude \(m\) of the wobble components \((m_1, m_2)\). Given that the amplitude of the wobble variable is typically of order 0.3 arc-seconds, the load deformation is typically no larger than about \((1.8, 0.5, 0.5)\) mm in (radial, north, east) component, but it may occasionally be larger.

### 7.2 Models for other non-conventional displacement of reference markers on the crust

It is envisioned that this section describes methods of modeling non-tidal displacements associated with changing environmental loads, e.g. from atmosphere, ocean and hydrology. For this purpose, models should be made available to the user community through the IERS Global Geophysical Fluid Center and its special bureaux, together with all necessary supporting information, implementation documentation, and software.

At the time of this registered edition of the *IERS Conventions*, it is recommended not to include such modeling in operational solutions that support products and services of the IERS. Nevertheless, the non-tidal loading effects can be considered in other studies, and this section will be updated as adopted models become available.

### 7.3 Models for the displacement of reference points of instruments

This section lists effects which are to be considered when relating the reference point of an instrument used in a given technique to a marker that may be used as a reference by other techniques. Typical examples are antenna phase center offsets. These effects are technique-dependent and the conventional models for these effects are kept and updated by the technique services participating to the IERS: The IVS <11> for very long baseline interferometry, the ILRS <12> for satellite laser ranging, the IGS <13> for global navigation satellite systems and the IDS <14> for DORIS. This section provides a short description of these models and directs the user to the original source of information.

#### 7.3.1 Models common to several techniques

As some of the effects depend on local environmental conditions, conventional models for these effects need to be based on a reference value for local temperature. A conventional model to determine reference temperature is given below.

**Reference temperature**

If necessary, it is recommended to determine the reference temperature values with the model GPT (Boehm et al., 2007) which is based on a spherical harmonic expansion of degree and order 9 with an annual periodicity, and is provided as a Fortran routine, GPT.F, at \(<15>\) and \(<16>\). The arguments of the routine are described in its header. The model assumes a yearly signature and no secular variation, so should not impact secular terms in the modeled geodetic data. If

16http://www.hg.tuwien.ac.at/~ecmwf1
only a constant reference temperature is needed (no yearly term), the model value at the 119th day of year, 07:30 UTC (e.g. MJD 44357.3125) should be used.

7.3.2 Very long baseline interferometry

Thermal expansion

VLBI antennas are subject to structural deformations due to temperature variations that can cause variations in the VLBI delay exceeding 10 ps. Correspondingly, the coordinates of the reference point may vary by several mm. For this reason the IVS has developed a model for VLBI antenna thermal deformation (Nothnagel, 2008) that is to be used in its routine product generation. The conventional model for VLBI antenna thermal deformation may be found at http://vlbi.geod.uni-bonn.de/IVS-AC/Conventions/Chapter1.html.

7.3.3 Global navigation satellite systems

Antenna phase center offsets and variations

The exact phase center position of the transmitting as well as of the receiving antenna depends on the line of sight from the satellite to the receiver. This anisotropy is modeled by a phase center offset from a physical reference point to the mean electrical phase center together with its corresponding elevation- and azimuth-dependent variations. Since November 2006, the IGS applies consistent absolute phase center corrections for satellite and receiver antennas (Schmid et al., 2007). The current model is available at ftp://igs.org/igscb/station/general/igs05.atx.
